

# Table of Contents

ProjX has some requirements for the session LCO. The application assumes that an object with the name **workScreenAccess** is present. There's another object with the name **helpStore**.

If you don't configure your session LCO correctly, your application will throw exceptions and won't work as expected.

Your session LCO should contain a method with the name

```
getWorkScreenAccess
```

Sometimes you won't, or can't, use the predefined object names. If that's the case, it's possible to change predefined object names:

Simply add the following annotation to your preferred method:

```
@Replacement(name = "workScreenAccess")
public IWorkScreenAccess getCustomWSAccess()
{
    ...
}
```

The predefined object names are:

- workScreenAccess
- helpStore
- translator
