If you start an application from another application or via command line, you could use command-line arguments to set application parameters like username/password. Of course, you shouldn't use this in production environments, but you could for test applications or unit tests.

It's really simple to set application parameters via command line (see Using Application Parameters):

To implement automatic login, simply set

```
Application.Login.username=username Application.Login.password=password
```

after the application class and **config** parameter:

```
java .-cp... com.sibvisions.apps.projx.ProjX /myapp/application.xml
Application.Login.username=...
```
